

## OPIM 201 Operations Management

### LINE BALANCING

# Learning Objective

- Understand **Line Balancing** and how it can help improve process efficiency for line-flow processes
  - Line Balancing: allocating tasks so as to balance the workload throughout the process while meeting the target flow rate – for a line-flow process

# Recall Subway Case: Hourly Demand of 90 Sandwiches

Ignore Task G,  
Toasting (oven)

|                  | Worker 1                                                                                                                                  | Worker 2                                  | Worker 3                                  |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|-------------------------------------------|
| Activity Time    | 37 seconds/unit                                                                                                                           | 46 seconds/unit                           | 37 seconds/unit                           |
| Capacity         | 1/37 unit per second<br>= 97.3 units/hour                                                                                                 | 1/46 unit per second<br>= 78.3 units/hour | 1/37 unit per second<br>= 97.3 units/hour |
| Process Capacity | Minimum {97.3, 78.3, 97.3 units/hour} = 78.3 units/hour                                                                                   |                                           |                                           |
| Flow rate        | Demand = 90 units/hour (Target CT = $60 \times 60 / 90 = 40$ seconds)<br>Flow rate = Minimum {demand, process capacity} = 78.3 units/hour |                                           |                                           |
| Utilization      | $78.3 / 97.3 = 80.5\%$                                                                                                                    | $78.3 / 78.3 = 100\%$                     | $78.3 / 97.3 = 80.5\%$                    |

The process is capacity-constrained. ( System CT (= 46 sec.) > Target CT (= 40 sec.) )

$$\text{Avg. labor utilization} = \frac{80.5 + 100 + 80.5}{3} \approx 87\%$$

$$\text{Labor cost per sandwich} = \frac{3 \text{ workers} \times \$12/\text{hr}}{78.3 \text{ units/hr}} = \$0.46/\text{unit}$$

# Hourly Demand: 90 Sandwiches

|                  | Task                      | Seconds   | 3+ Support      |
|------------------|---------------------------|-----------|-----------------|

| Total Seconds    |                           | 120 - 150 |                 |
| Support Position | Phone/Fax Orders          |           | 4               |
|                  | Baking Bread/Cookies      |           |                 |
|                  | Filling In on Line        |           |                 |
|                  | Restocking Sandwich Unit  |           |                 |
|                  | Cleaning Customer Area    |           |                 |

| Station | Activity Time (s) |
|---------|-------------------|
| 1       | 37                |
| 2       | 46                |
| 3       | 37                |

Flow Rate = 78.3 units/hr

Target CT = 40 seconds

How can one increase the production to meet demand?

- Further job specialization at Station 2 (need to add worker)
- Line (Re)Balancing
  - Can we arbitrarily move task(s) from bottleneck to non-bottleneck(s)?

# Line Balancing Can Be Very Complex

BOEING 737 has almost 6 million parts

How do we perform line balancing or design a line?

Ad hoc approach? Systematic approach?

# Production Levelling

- **Production Levelling (Smoothing)**: Setting a constant production (or target demand) rate for a given period of time. Reasons:
  - Planning purposes (e.g. determining staffing plan)
    - Planning becomes too complex if actual demand variation is incorporated.
  - Production consistency and efficiency. (How?)
- Facilitated by Demand Levelling and Staffing to Demand
  - Demand levelling: deliberate influencing of demand to mitigate demand fluctuation.
  - Staffing to Demand: Adjusting capacity to meet demand.
    - **Line Balancing**: Allocate activities so as to balance the workload across the process while meeting the target demand.
      - ♦ Consider automating time-consuming activities, outsourcing activities, adding employees, overtime.
      - ♦ Consider Specialization: Breaking down task (especially bottleneck).
- **Capacity Flexibility** is crucial as target demand rate may vary across periods.
  - Need a long-term perspective – Cross-training, temporary or flexible workforce

# Line Balancing and Staffing to Demand

## Actual Demand

## Leveled Target Demand

## Cycle time

## Resource planning

## CT 2 minutes

## CT 1 minute

## Capacity flexibility

Ability to adjust to changing demands

Often implemented with temporary workers

Keeps average labor utilization high

# Line Balancing – Problem Description

- Assign all tasks to a sequence of workstations.
- Objective:
  - Minimize number of workstations;
    - Maximize the overall labor/machine utilization for a given production rate/flow rate;
  - Minimize idle time across all workstations (a “good” balance).
- Constraints:
  - Target cycle time or flow rate requirement; (recall  $R = 1/CT$ )
  - Precedence relationship (specifies the order in which tasks must be performed).

Processing time at every station is no more than Target CT

# Basic Line Balancing Vocabulary

- (Target) Cycle time, CT : the time between successive units coming off the end of the line.
- Task time,  $t_k$  : time it takes to complete task k
- A task is **eligible** to be included in a workstation, if all its preceding tasks have been included in the current or prior workstations.

# Line Balancing Example – Huffy

Huffy assembles bicycles on a conveyor belt and operates one shift (8 hours) per day. Currently its daily forecast is 220 bicycles and its daily production plan is 225 bicycles. Perform a line balance of the assembly line that achieves the target production rate with the following tasks to be performed on the line:

| Task | Time (sec.) | Predecessor |
|------|-------------|-------------|
| 1    | 60          | None        |
| 2    | 45          | 1           |
| 3    | 35          | 1           |
| 4    | 92          | 3           |
| 5    | 55          | 3           |
| 6    | 70          | 2, 4        |
| 7    | 30          | 6           |
| 8    | 25          | 5, 6        |
| 9    | 65          | 7, 8        |

Total 477

What is the target production rate?

# The Precedence Diagram

The Precedence Diagram depicts the Precedence Relationship.

**Task**   **Predecessors**

1          None

2          1

3          1

4          3

5          3

**Task**   **Predecessors**

6          2, 4

7          6

8          5, 6

9          7, 8

# Compute Target CT

$$\begin{aligned}\text{Target CT} &= 1/225 \text{ day per unit} \quad (R = 225 \text{ units/day}) \\ &= (8 \text{ hr/day})(60 \text{ min/hr})(60 \text{ sec/min}) / 225 \text{ units} \\ &= 128 \text{ sec. per unit}\end{aligned}$$

# Two Heuristics (Priority Rules) for Line Balancing:

- Primary rules
  - Longest Task Time (LTT) rule
    - Assign tasks (that fit within the remaining time constraint) in order of the longest task time
  - Largest Number of Followers (LNF) rule
    - Assign tasks (that fit within the remaining time constraint) in order of the largest number of following tasks
- Tie breaker
  - When applying a priority rule, if two or more tasks are tied with same priority value, then use the other priority rule as a tie breaker

*The above two are heuristics; they don't necessarily find the minimum number of workstations for a target productivity.*

# LTT Heuristic

| Workstation | Time Remaining  | Eligible       | Assign      | Idle |
|-------------|-----------------|----------------|-------------|------|
| 1           | 128<br>68       | 1<br>2, 3      | 1<br>2      | 23   |
| 2           | 128<br>93       | 3<br>4, 5      | 3<br>4      | 1    |
| 3           | 128<br>58       | 5, 6<br>5, 7   | 6<br>5      | 3    |
| 4           | 128<br>98<br>73 | 7, 8<br>8<br>9 | 7<br>8<br>9 | 8    |
| Total       |                 |                |             | 35   |

Optimal?

# Theoretical Minimum Number of Workstations

$$N_{\min} = \sum t_k / CT \quad (t_k = \text{task time of task } k)$$

$$= 477 \text{ sec.} / 128 \text{ sec.}$$

$$= 3.73 \text{ or } 4 \text{ workstations}$$

Can be interpreted  
as Target Manpower

Can't do better than 4 stations!

Total task time = 477 sec

128 sec

128 sec

128 sec

93 sec

# LTT Heuristic (cont'd)

- Rationale of LTT?
- Comment on the task allocation.
- What do you think of the idle time?

Idle time in all stations!  
Reduce CT & idle time?

| Workstation | Time Remaining  | Eligible       | Assign      | Idle |
|-------------|-----------------|----------------|-------------|------|
| 1           | 128<br>68       | 1<br>2, 3      | 1<br>2      | 23   |
| 2           | 128<br>93       | 3<br>4, 5      | 3<br>4      | 1    |
| 3           | 128<br>58       | 5, 6<br>5, 7   | 6<br>5      | 3    |
| 4           | 128<br>98<br>73 | 7, 8<br>8<br>9 | 7<br>8<br>9 | 8    |
| Total       |                 |                |             | 35   |

# Addressing Idle Time ...

- Make workers spend idle time on quality control/background processing
- Cross-trained workers to help busy workers
- Redesign process

# LNF Heuristic

- LNF inferior?
- Rationale of LNF rule?

| Workstation | Time Remaining  | Eligible          | Assign        | Idle |
|-------------|-----------------|-------------------|---------------|------|
| 1           | 128<br>68       | 1<br>2, 3         | 1<br><b>3</b> | 33   |
| 2           | 128             | <b>2, 4, 5</b>    | 4             | 36   |
| 3           | 128<br>83       | 2, 5<br>5, 6      | 2<br>6        | 13   |
| 4           | 128<br>73<br>43 | 5, 7<br>7, 8<br>8 | 5<br>7<br>8   | 18   |
| <b>5</b>    | 128             | 9                 | 9             | 63   |
| Total       |                 |                   |               | 163  |

# Efficiency of the Line Flow for Huffy Under LNF Heuristic

■ **Efficiency** =  $\frac{\sum t_k}{N_a \times CT}$

Total workload or busy time or what actually gets done

Maximum workload allowed or available time or what theoretically can get done

$$= \frac{477}{5 \times 128}$$

$$= 0.745 \text{ or } 74.5\%$$

- $N_a$  = actual number of workstations
- Efficiency can be interpreted as the average utilization of the line; hence it's also equal to the average utilization of all workstations.

# Maximum Production Rate?

The *minimum* cycle time of the line, and therefore, the maximum production rate is determined by task 4 (bottleneck task)

Assume operating 1 shift (8 hrs) per day.

$$\begin{aligned}\text{Max Production} &= 1/92 \text{ units per sec} \\ &\approx 313 \text{ units per day}\end{aligned}$$

*Note that target production may not equal maximum production.*

# Remarks

- The LTT and LNF are heuristics; they don't necessarily find the OPTIMAL solution
- However, if in a solution, the number of stations is equal to the *theoretical minimum number of stations*, then the solution is optimal and efficiency is optimized
- Optimal number of stations may be more than theoretical minimum due to
  - Discrete values of task time
  - Precedence relationship
- Other heuristics?

# Basic Line Balancing Vocabulary

- (Target) Cycle time, CT : the time between successive units coming off the end of the line.
- Task time,  $t_k$  : time it takes to complete task k
- A task is **eligible** to be included in a workstation, if all its preceding tasks have been included in the current or prior workstations.
- Efficiency =  $\frac{\text{total task time}}{N_a \times \text{cycle time}}$ , where  $N_a$  = actual number of workstations
- Theoretical minimum number of stations,  $N_{\min}$ : The theoretical minimum number of stations required to achieve the target flow rate or CT.
  - Calculate the ratio of total task time to the cycle time,  $\frac{\text{total task time}}{\text{cycle time}}$ , and round it up.
  - Optimal number of stations required could be more due to discrete values of task times, precedence relationships and other restrictions.

# General Procedure for Line Balancing

- **Step 1**
  - Create a new station numbered  $k$  with station time = 0
- **Step 2**
  - List all eligible tasks. If there are no eligible tasks, stop (final cycle time = largest station time, number of workstations = current value of  $k$ ).
- **Step 3**
  - Select the first eligible task according to a specified priority rule. If (task time + current station time)  $\leq$  cycle time, go to step 5. Otherwise, go to step 4.
- **Step 4**
  - Ignore this eligible task. If there are more eligible tasks, return to step 3 otherwise increase  $k$  by 1 and return to step 1.
- **Step 5**
  - Remove the task from the eligible list, add it to the current station. Increment current station time by the task time, find new eligible tasks and return to step 2.
